

Report Documentation Page				Form Approved OMB No. 0704-0188	
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

LONG-TERM GOALS

The purpose of this study is to understand the feasibility of forecasting the dynamics of the generation and life cycle of large amplitude internal waves and their impact on the larger scale flow. The forecasting system may include imbedded nonhydrostatic models, subgrid scale models or subgrid scale parameterizations in hydrostatic models. The scope of the dynamics and the resolution which can be included in a forecast system will be explored.

This work will provide the understanding needed to build an operational system to predict the timing, location and intensity of NLIWs as required for tactical planning.

OBJECTIVES

- To investigate the generation, development, propagation and interaction of IWs and NLIWs in straits using nonhydrostatic and hydrostatic models.
- To hindcast these NLIWs using high resolution nonhydrostatic and hydrostatic numerical models with realistic ocean topography and surface forcing and using open boundary conditions provided by the large scale ocean model.

APPROACH

Simulations and hindcasts have been conducted on massively parallel HPC machines. We are developing a system of nested hydrostatic and nonhydrostatic model domains that allows us to achieve the necessary resolution with the correct physics to hindcast submesoscale processes. The system efficiently utilizes data from the NCOM and COAMPS models as forcing and initial conditions for the MITgcm model. The system also allows us to multiply nest the MITgcm model to achieve high resolution hindcasts. We have the capability and the infrastructure to conduct large scale, high resolution numerical experiments on high performance, massively parallel computers.

WORK COMPLETED

We have formulated a combined open boundary condition consisting of a Transport Correction Scheme (TCS) for incoming fluxes to conserve volume, and a Flow Relaxation Scheme (FRS) to

match outgoing and incoming fluxes. We have developed and tested methods using hindcasts of regions in the South China Sea.

Transport Correction Scheme (TCS). Open boundary conditions are formulated to conserve volume by matching the change in SSH and the total transport through the lateral boundaries and distributing the difference into the baroclinic transports.

Flow Relaxation Scheme (FRS). Additional open boundary conditions are constructed to prevent reflections and perimeter currents generated when flows do not exit the interior domain correctly. The FRS is optimized to minimize the spurious kinetic energy in the interior domain.

RESULTS

Large discrepancies at the boundaries between the exterior and interior domains are caused by differences in physics (nonhydrostatic versus hydrostatic) and differences in resolution. These differences can cause unrealistic interior solutions with incorrect long term trends, and spurious reflections and perimeter currents at the boundaries. We have extended and improved two open boundary condition methods which together correct these problems and we have implemented them in the MIT model. This significantly expands the boundary conditions in the MIT model. A paper has been submitted to Ocean Modelling detailing the improved BCs.

IMPACT/APPLICATIONS

This work will help to determine the importance of and the requirements for nonhydrostatic forecast systems for naval applications. The scales and features which will require nonhydrostatic simulation are being assessed.

RELATED PROJECTS

The NRL project Autonomous Characterization of Environmentally Induced Non-Acoustic Noise and the Adaptation of Multi-Sensor USW Networks. (6.2, Undersea Warfare) is related to this project because it involves nonhydrostatic modeling of the SW06 experimental area and time and comparison with measurements taken during SW06. Components of SW06 are funded through the ONR NLIWI DRI.
